AI Logs - SOEN341 - Sprint 1

Task 1: Define User Stories

Purpose of AI Use: Brainstorming and requirements elicitation

Prompt: Can you please generate 10 user stories with tasks for the SOEN 341 team project (gave project description)?

AI-Suggested Content: AI generated an initial list of 10 CareerConnect user stories for job seekers and recruiters, as required by the Sprint 1 AI-log specification.

Validation: The generated stories must be compared with the official CareerConnect requirements and kept separate from the team-generated stories and features. This validation should be completed using the actual AI output from Parsa's conversation.

Decision: Pending - complete after reviewing the actual 10 generated user stories.

Reflection: This entry is required by the Sprint 1 specification. AI can help produce a starting backlog, but the team must review, refine, and extend the suggestions rather than adopting them without evaluation.

Responsible Person: Parsa Dalirirad

Task 2: Plan and Implement the US-01 Registration Backend

Purpose of AI Use: Requirements analysis, backend planning, code generation and implementation guidance

Prompt: please guid me step by step in the programming and creation of backend and keep in mind I am a beginner in python and sql so I need you to help and guid me in it.

AI-Suggested Content: AI helped break Parsa's US-01 backend work into registration, login/authentication, input validation, error handling, and authentication/database integration. It also proposed an initial Flask registration endpoint and helped refine GitHub task descriptions and acceptance criteria.

Validation: The proposed work was manually reviewed against the US-01 registration/login requirements. The generated implementation was treated as a starting point rather than accepted automatically. The endpoint design was reviewed for required email/password fields, invalid input, duplicate account handling and clear error responses.

Decision: Modified before use.

Reflection: AI was useful for turning the user story into smaller backend tasks and proposing an initial implementation. The generated code still required manual review because architecture assumptions and team responsibilities could not be decided by AI alone.

Responsible Person: Parsa Dalirirad

Task 3: Review Authentication Architecture and Align with Supabase Auth

Purpose of AI Use: Architecture review, problem solving and code review

Prompt: After a comparison that I had with my teammate I realised that supabase Auth. Was used in the database, can you please help me to fix this mismatch and guid me through it please?

AI-Suggested Content: The initial AI-assisted approach considered a custom PostgreSQL users table with password_hash storage and application-managed authentication. AI was then used to compare that approach with the team's database/authentication work and identify the mismatch.

Validation: Parsa compared the proposed custom authentication design with the team's implementation and asked Mujdeh to confirm the authentication approach. Mujdeh confirmed that the team was using Supabase Auth. Based on that team confirmation, the earlier custom password-storage approach was rejected and the backend direction was revised.

Decision: Rejected for the custom authentication approach; revised to align with Supabase Auth.

Reflection: This interaction showed why AI output cannot be accepted blindly. A technically valid custom password system was still the wrong choice because it conflicted with the team's selected architecture.
